Operating System Configuration

I reviewed and configured the display, power, and accessibility settings in the Windows Server 2025 environment. I adjusted the display options, checked the power settings, and changed accessibility features that make navigating the system easier. These configurations help create a working environment with my preferences.

Users Account

I created an additional local user account named Someone. This account has a description and a password that will not expire. This account was assigned to the Remote Desktop Users and Users groups. But there was an issue with logging into this account so I added the account to the Remote Desktop Users group to resolve the issue.

Password Configuration/Security Settings

I reviewed the Windows Security settings to verify that the virtual machine's security features were enabled and up to date. Virus and threat protection showed no action needed. Ransomware protection also required no action. I verified that the firewall was enabled for the Domain, Private, and active Public networks. Core Isolation and Secure Boot were also enabled to provide additional protection against potential security threats.

Windows Update Verification

I checked Windows Update to verify that the Windows Server 2025 environment was on the latest update. I reviewed the update status and installed any updates that were available. Keeping the operating system updated helps maintain system security, stability, and performance.

Application Installation

The three applications I chose to install were Google Chrome, 7-zip, and Notepad++. After installing these applications, I configured some changes on each of the applications. I did these changes to better suit my preferences.

System Verification

After reviewing the operating system and changes to the application's configurations, I performed verification tests to ensure it is functioning properly. I tested all three applications to confirm they opened successfully. I also verified that the additional local user account could log in and that network connectivity was operational. Lastly, I restarted the virtual machine and confirmed that I could log back into the system.
